

# Clues on Elliptical galaxy formation from SDSS galaxy profiles

M. Bernardi, A. Meert et al.  
UPenn

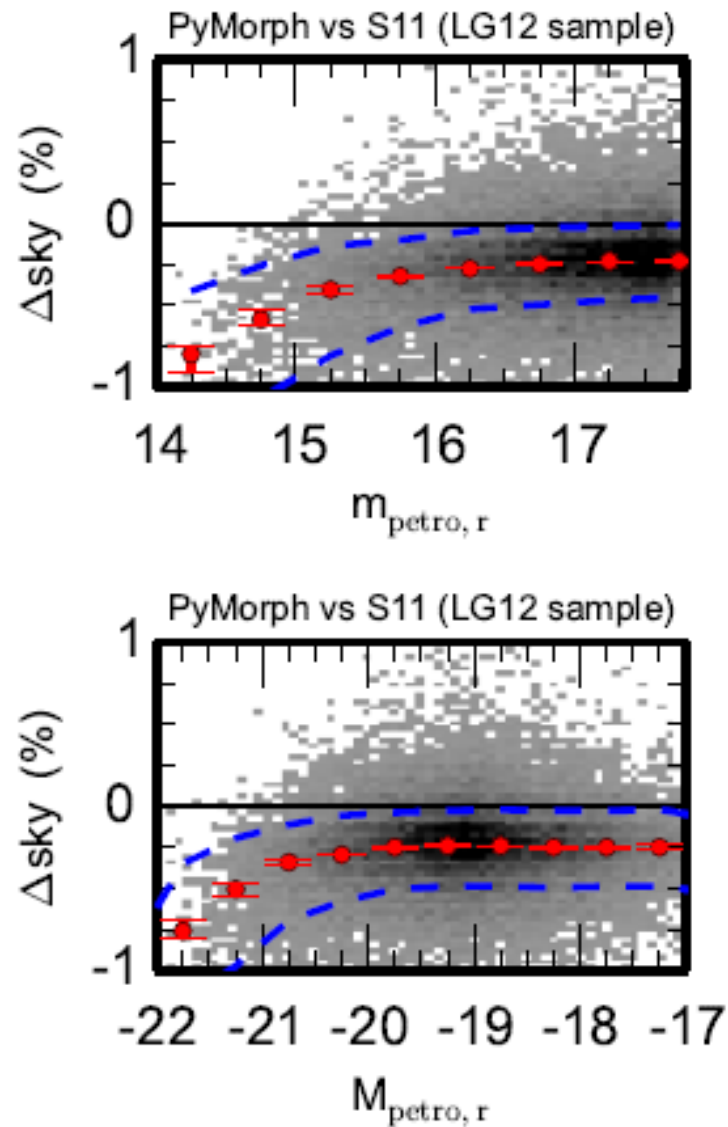

# Better photometry of the SDSS brightest galaxies .....

- Dependence on fitting model
- Dependence on sky

Bernardi et al. 2013

# Dependence on sky

# Sky subtraction problems also affect $n_{\text{Ser}}$

Bernardi et al 2014a

Simard et al. (2011)

# Welcome to the UPenn SDSS PhotDec Catalog!

$z = 0.09$   
 $P_{\text{ell}}(\text{Ell}) = 0.06$   
 $P_{\text{ell}}(\text{Spiral}) = 0.94$   
 $P(\text{Ell}) = 0.01$   
 $P(\text{S0}) = 0.05$   
 $P(\text{Sab}) = 0.80$   
 $P(\text{Scd}) = 0.14$   
 $M_{\text{core}} = -21.273$   
 $m_{\text{core}} = 16.878$   
 $B/T_{\text{core}} = 0.54$   
 $f_{\text{d,core}} = 2.77$   
 $f_{\text{bulge,core}} = 2.94$   
 $f_{\text{disk,core}} = 5.11$   
 $p_{\text{bulge,core}} = 88.40$   
 $p_{\text{disk,core}} = 90.68$   
 $b_{\text{bulge,core}} = 0.50$   
 $b_{\text{disk,core}} = 0.23$   
 $\text{sky}_{\text{core}} = 2.3743$

Meert, Vikram & Bernardi (arXiv:1406.4179)

**!!THIS IS A PAID COMMERCIAL ANNOUNCEMENT!!**

Note: The 1d data is calculated using background-subtracted data. The 2d data is shown with background included.

The UPenn SDSS PhotDec Catalog provides 2-d galaxy profile fits in several visible bands using SDSS data. Additional data collected from other sources is provided to facilitate analysis. The catalog is constructed and maintained by Mariangela Bernardi, Alan Meert and Vinu Vikram. To learn more about the catalog visit the other sections.

#### 1D Legend

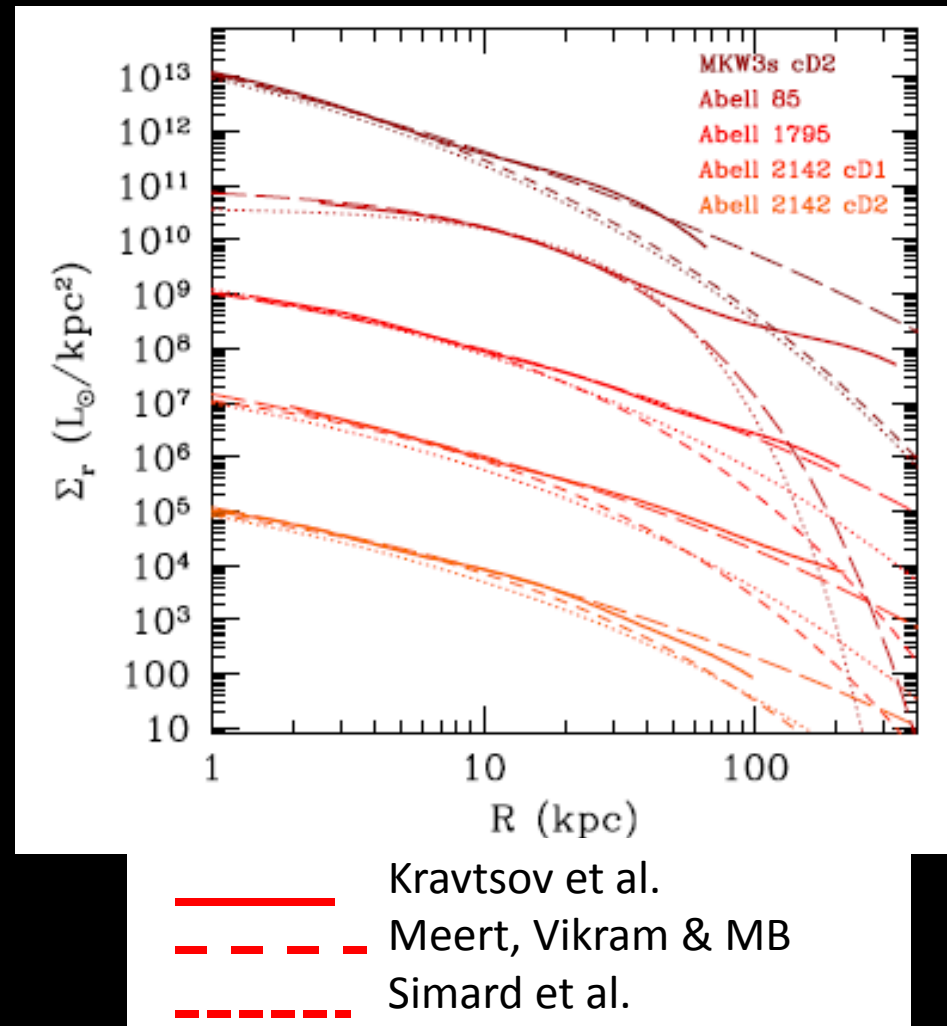

- data data
- serexp total
- - serexp bulge
- ... serexp disk
- - full sky
- ... 1% sky
- -  $r_M$

# Measurements in close agreement with other photometry of nearby clusters

Kravtsov et al. 2014

# Luminosity Function

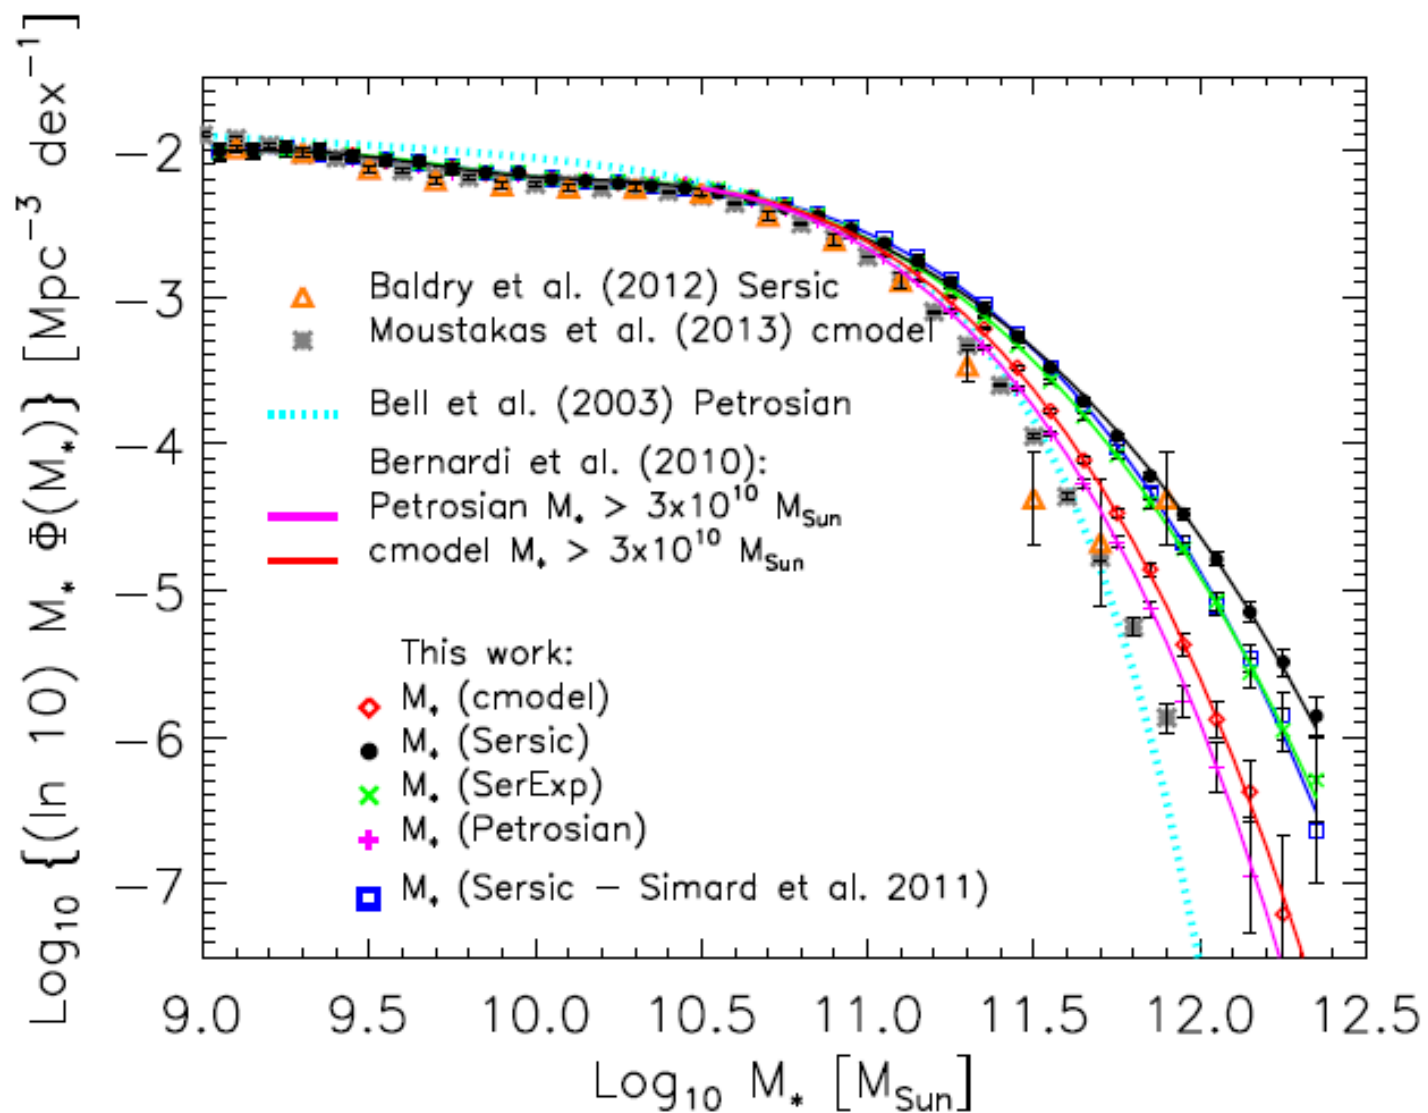

Bernardi et al. 2013

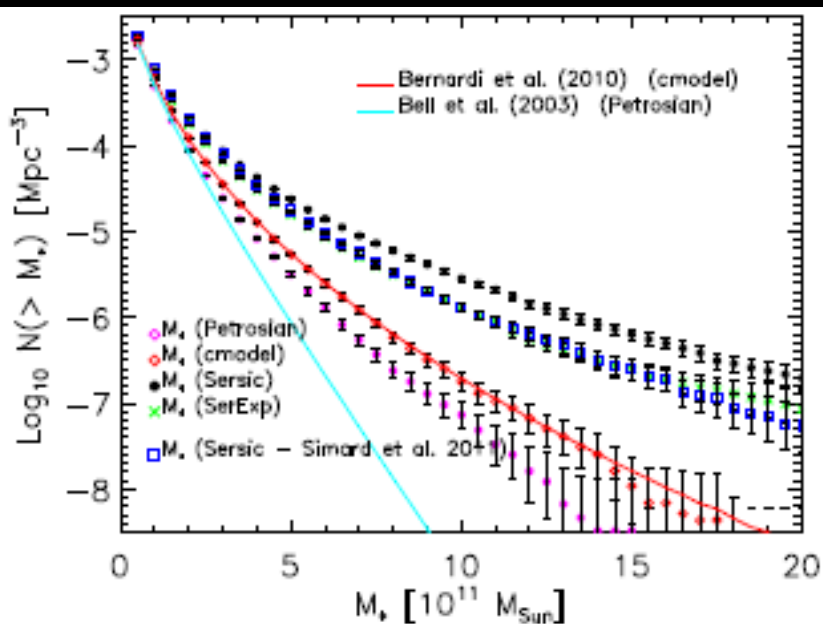

# M\* Function

Bernardi et al. 2013

## Bernardi et al. (2013)

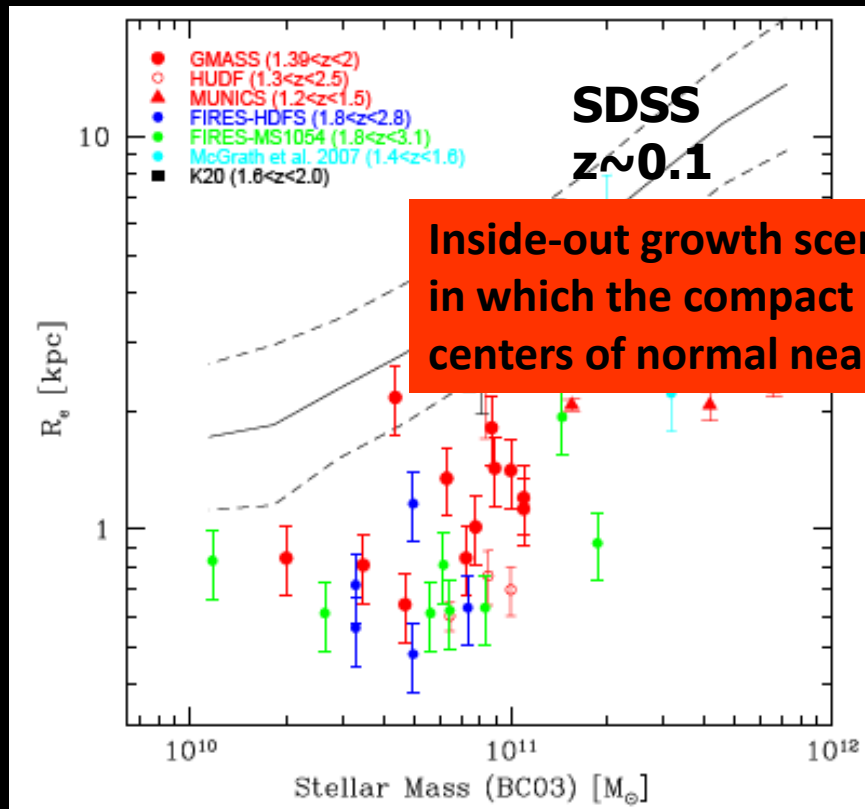

## Kravtsov et al. (2014)

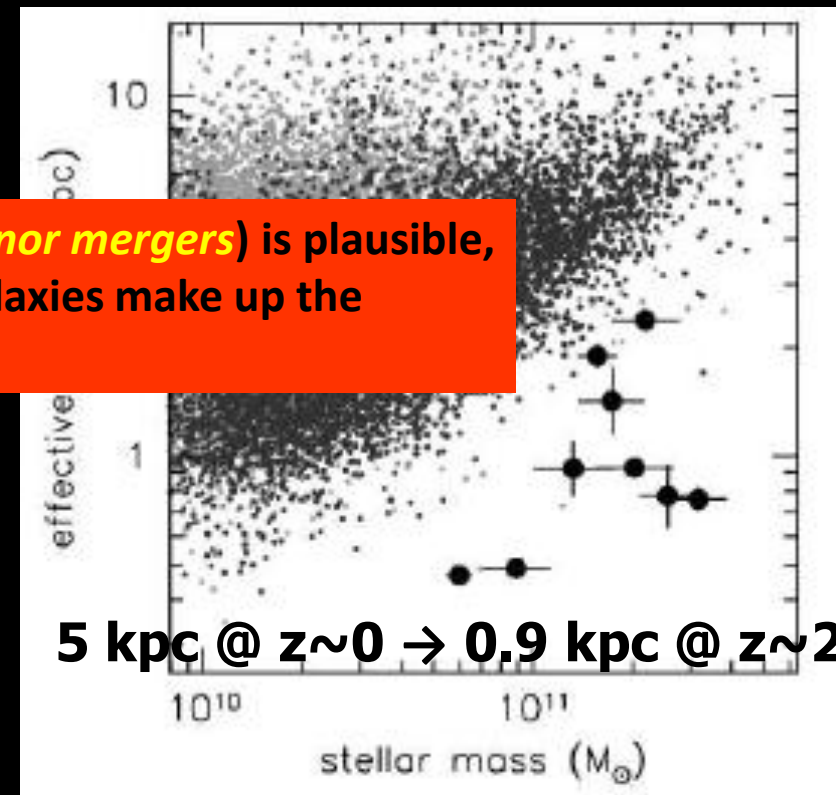

- impacts HOD/SHAM  $M^*-M_{\text{halo}}$  relations
- reduces required feedback at high  $M$

# The assembling of massive galaxies and the growth of sizes .....

At fixed stellar mass, high- $z$  sizes are smaller by  $(1+z)^{-1}$  or more (e.g. Trujillo et al. 2007; Cimatti et al. 2008; van Dokkum et al. 2008; Saglia et al. 2011; Bruce et al. 2012; Fan et al. 2013)

Inside-out growth scenario (*minor mergers*) is plausible, in which the compact high  $z$  galaxies make up the centers of normal nearby Es.

5 kpc @  $z \sim 0 \rightarrow 0.9$  kpc @  $z \sim 2$

Cimatti et al. 2008

van Dokkum et al. 2008

Two scales are important:  $3 \times 10^{10}$  and  $2 \times 10^{11} M_{\text{Sun}}$

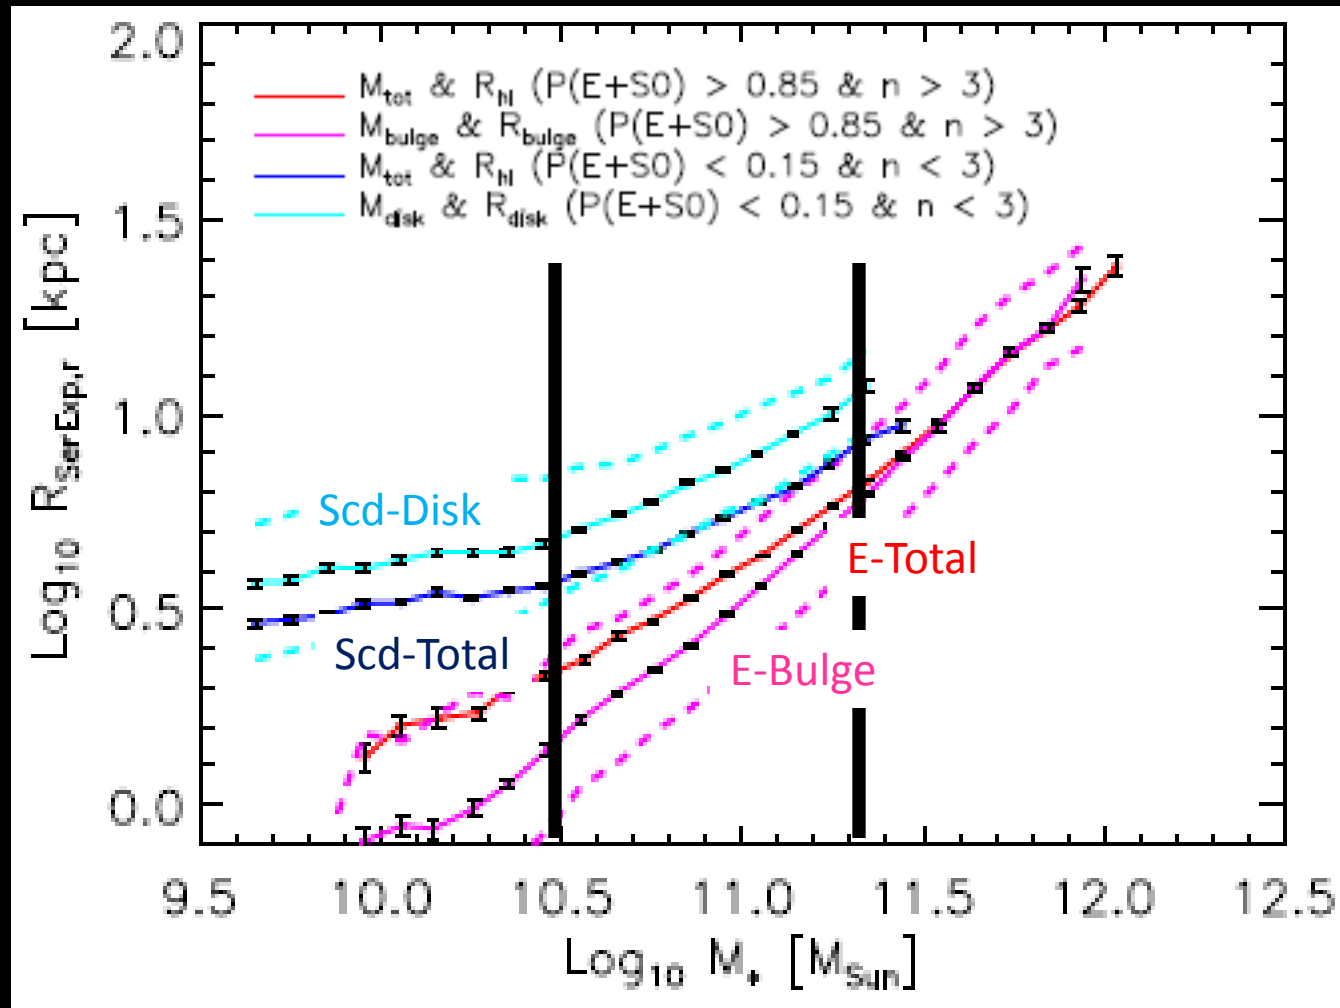

Wet mergers

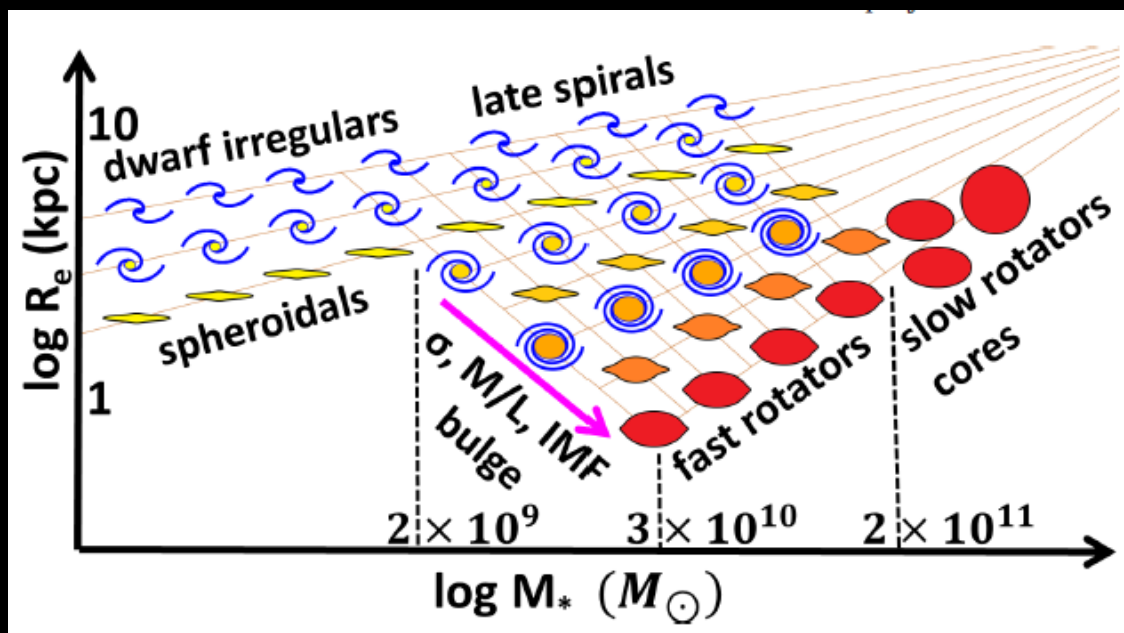

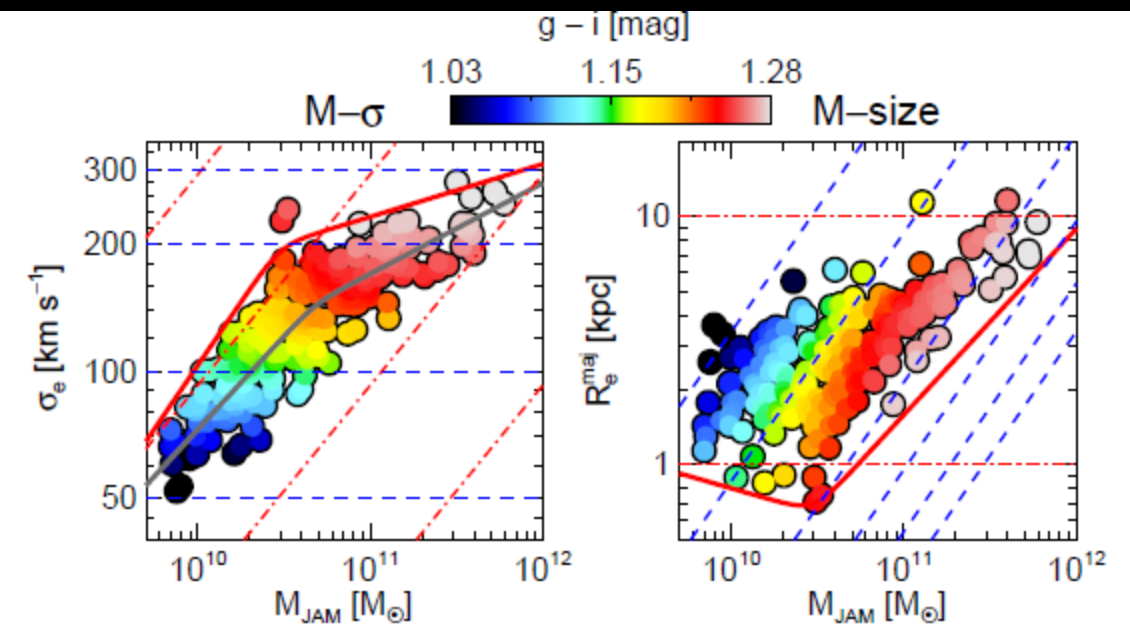

Dry mergers:  
Major or minor?

# The two mass scales are important also for the bulge and disk $M^*$ -R relation

Bernardi et al. 2014a

# Minor vs Major dry mergers

Using the Sersic profile

Hilz et al. (2013)

# Minor vs Major dry mergers

Hilz et al. (2013)

Hilz et al. (2012)

Effective radius evolution

$n_{\text{Ser}}$  shows largest change

$n_{\text{Ser}}$  evolution

Velocity dispersion evolution

# The two mass scales: $3 \times 10^{10}$ & $2 \times 10^{11} \text{ M}_{\text{sun}}$

Bernardi et al. 2014b

Also in  $n_{\text{Ser}}$  !!

# Analysing $n_{\text{Ser}}$

At fixed  $M_*$  larger  $n_{\text{Ser}}$  have smaller  $\sigma$

But we should look at B/T

# The high mass scale: $2 \times 10^{11} M_{\text{sun}}$

Bernardi et al. 2014b

A break for a disk component and increased evidence of minor dry mergers

Bulge component

# At fixed $M_*$ larger $n_{\text{Ser}}$ have higher SSFR

# How did the compact high-z galaxies evolve?

Evolution of  $n_{\text{Ser}}$ ,  $\sigma$  and  $M_*$

## Evolution of $R_e$ , $n_{\text{Ser}}$ , and $M_*$

Evolution of  
 $R_e$ ,  $n_{\text{Ser}}$ ,  $\sigma$  and  
 $M_*$

Number density of compact galaxies

van der Wel et al. 2014

Bernardi et al. 2014b

In addition larger  $n_{\text{Ser}}$   
have higher SSFR ....

# Dependence on Halo Mass (using the Yang et al. catalog)

Bernardi et al. 2014b

- Not completely trivial
- Yang et al. have no scatter in  $L_{\text{tot}}$  vs  $M_{\text{halo}}$  and very low scatter in  $L_{\text{cen}}$  vs  $M_{\text{halo}}$  especially at low  $M_{\text{halo}}$
- Simply using our new  $L_{\text{tot}}$  gives spurious results, so
  - We rank order in our new  $L_{\text{tot}}$  and assign  $M_{\text{halo}}$  accordingly; this will alter  $V_{\text{halo}}-M_{\text{halo}}$  relation
- We also account for fact that new  $L$ s sometime mean another object in group is brightest; we define 'central' to be brightest

# Analysing $n_{\text{Ser}} - M_* - M_{\text{halo}}$

ONLY CHANGE L

CHANGE L AND RE-SORT  $L_{\text{tot}}$

# Analysing $n_{\text{Ser}} - M_* - M_{\text{halo}}$

At fixed  $M_*$   
centrals in  
larger  $M_{\text{halo}}$   
have smaller  
 $n_{\text{Ser}}$

# Central vs Satellites

Small difference  
in SSFR

# Conclusions from our fitting profiles:

- Sky-subtraction + Sersic/SerExp fits suggest more objects at  $M_* > 2e11$  than previous work:
  - impacts HOD/SHAM  $M^*$ - $M_{\text{halo}}$  relations
  - reduces required feedback at high  $M$
  - alleviates tension between  $\rho_*$  and  $\text{SFR}(z)$
- Two mass scales are important:  $3e10$  and  $2e11$ :  $M_* > 2e11$  special even more pronounced in  $n$ - $M_*$ 
  - Difference between total and bulge dramatic at  $M_* < 2e11$  (suggestive of fast/slow rotator dichotomy)
- Sersic  $n > 6$  at  $M_* > 2e11$  suggestive of minor dry mergers
  - $n$ - $\sigma$  at fixed  $M_*$  particularly useful
  - At fixed  $M^*$  smaller  $\sigma$  have larger  $n$ ; larger SSFR have larger  $n$ ; smaller  $M_{\text{halo}}$  have larger  $n$
  - Evolution of compact high- $z$  galaxies  $\Rightarrow$  high  $n_{\text{Ser}}$  galaxies at  $z \sim 0$ ?  
Evidence of minor mergers?
